Subject:

Capt xxxx,

Thanks for responding.

I'm reaching out to communicate some information relative to COVID that I don't believe xxxx or your director is aware of. You probably saw earlier this week that more official documents linking NIH and EcoHealth Alliance to the Wuhan Institute of Virology were published by The Intercept. I came across additional incriminating documents and produced an analysis shortly after leaving DARPA last month. This report was routed to the DOD IG office.

I'm unsure whether the significance of what I communicated is understood by those that received the report. Decisions with regards to the vaccines do not appear to be informed by analysis of the documents. The main points being that SARS-CoV-2 matches the SARS vaccine variants the NIH-EcoHealth program was making in Wuhan; that the DOD rejected the program proposal because vaccines would be ineffective and because the spike proteins being inserted into the variants were deemed too dangerous (gain-of-function); and that the DOD now mandates vaccines that copy the spike protein previously deemed too dangerous. To me, and to those who informed my analysis, this situation meets no-go or abort criteria with regards to the vaccines until the toxicity of the spike protein can be investigated. There's also information within the documents about which drugs effectively treat the program's SARS-CoVs.

Thus why I'm reaching out. I'm trying to help DOD leadership grapple with the vaccines and the mandate with as much information as is available. I wanted to push this information your way.

Several of the documents referenced in the IG report have since been downgraded.

Please reach out to me with questions.

V/R,

Major Joe Murphy USMC

1. SARS-CoV-2 is an American-created recombinant bat vaccine, or its precursor virus. It was created by an EcoHealth Alliance program at the Wuhan Institute of Virology (WIV), as suggested by the reporting surrounding the lab leak hypothesis. The details of this program have been concealed since the pandemic began. These details can be found in the EcoHealth Alliance proposal response to the DARPA PREEMPT<sup>11</sup> program Broad Agency Announcement (BAA) HR00118S0017, dated March 2018<sup>11</sup> – a document not yet publicly disclosed.

The contents of the proposed program are extremely detailed. Peter Daszak lays out step-by-step what the organization intends to do by phase and by location. The primary scientists involved, their roles, and their institutions are indicated. The funding plan for the WIV work is its own document. The reasons why nonpharmaceutical interventions like masks and medical countermeasures like the mRNA vaccines do not work well can be extrapolated from the details. The reasons why the early treatment protocols work as curatives are apparent.

SARS-CoV-2's form as it emerged is likely as a precursor, deliberately virulent, humanized recombinant SARS-CoV that was to be reverse engineered into a live attenuated SARS-CoV bat vaccine. Its nature can be determined from analysis of its genome with the context provided by the EcoHealth Alliance proposal. Joining this analysis with US intelligence collections on Wuhan will aid this determination.

UNCLASSIFIED

UNCLASSIFIED

When synthesized with the EcoHealth Alliance proposal, US collections confirm EcoHealth Alliance was performing the work proposed. The analysts produce their reports in a vacuum, absent the context the proposal provides. As a fellow at DARPA, I could see both, and can do the synthesis. For instance, WIV personnel identified in intelligence reports are named in the proposal, these people use the lexicon of the proposal in the collections, and the virus variants proposed for experimentation are identical to those gleaned by collections. Moreover, I am also privy to information obtained by congressional office investigators and by DRASTIC<sup>iv</sup>, which further corroborates that the program detailed in the BAA response was conducted until it was shut down in April 2020.

The purpose of the EcoHealth program, called DEFUSE in the proposal, was to inoculate bats in the Yunnan, China caves where confirmed SARS-CoV's were found. Ostensibly, doing this would prevent another SARS-CoV pandemic; the bats' immune systems would be reinforced to prevent a deadly SARS-CoV from emerging. The specific language used is "inoculate bats with novel chimeric polyvalent spike proteins to enhance their adaptive immune memory against specific high-risk viruses."<sup>vii</sup> Being defense-related, it makes sense that EcoHealth submitted the proposal first to the Department of Defense, before it settled with NIH/NIAID. The BAA response is dated March 2018 and was submitted by Peter Daszak, president of EcoHealth Alliance.

DARPA rejected the proposal because the work was too close to violating the gain-of-function (GoF) moratorium<sup>viii</sup> despite what Peter Daszak says in the proposal (that the work would not<sup>viii</sup>). As is known, Dr. Fauci with NIAID did not reject the proposal. The work took place at the WIV and at several sites in the US, identified in detail in the proposal.<sup>ix</sup>

The EcoHealth Alliance response to the PREEMPT BAA is placed along with other proposal documents in the PREEMPT folder on the DARPA Biological Technologies Office JWICS (top secret) share drive, address: Network/filer/BTO/CI Folder/PREEMPT

This folder was empty for a year. The files, completely unmarked with classification or distribution data, were placed in this folder in July 2021, which conspicuously aligns with media reporting, my probing, and Senator Paul's inquiry into NIH/NIAID gain-of-function programs. The unmarked nature combined with the timing signals that the documents were being hidden. No files at DARPA go unmarked in classification or distribution, including proprietary documents. Furthermore, PREEMPT is an unclassified program.

The files are also now held by Marine Corps Intelligence Activity (MCIA). They are identified in the reference block above.

2. SARS-CoV-2, hereafter referred to as SARS-CoV-WIV, is a synthetic spike protein chimera engineered to attach to human ACE2 receptors and

UNCLASSIFIED

UNCLASSIFIED

inserted into a recombinant bat SARSr-CoV backbone. It is likely a live vaccine not yet engineered to a more attenuated state that the program sought to create with its final version. It leaked and spread rapidly because it was aerosolized so it could efficiently infect bats in caves, but it was not ready to infect bats yet, which is why it does not appear to infect bats. The reason the disease is so confusing is because it is less a virus than it is engineered spike proteins hitch-hiking a ride on a SARSr-CoV quasispecies swarm. The closer it is to the final live attenuated vaccine form, the more likely that it has been deattenuating since initial escape in August 2019.

The utility of certain countermeasures can be extrapolated from the documents:

- The team selected for SARSr-CoV that were most monoclonal antibody and vaccine resistant.
- It is not practical to inoculate bats directly with shots, nor can bats get respiratory infections from droplets, so the team developed an aerosol to deliver the inoculations directly into the caves. To ensure it worked well, they developed the aerosol against masked rhesus monkeys.
- The proposal notes that interferon, Remdesivir, and chloroquine phosphate inhibit SARSr-CoV viral replication.

Because of its (now) known nature, the SARSr-CoV-WIV's illness is readily resolved with early treatment that inhibits the viral replication that spreads the spike proteins around the body (which induce a harmful overactive immune response as the body tries to clear the spikes from the ACE2 receptors). Many of the early treatment protocols ignored by the authorities work because they inhibit viral replication or modulate the immune response to the spike proteins, which makes sense within the context of what EcoHealth was creating. Some of these treatment protocols also inhibit the action of the engineered spike protein. For instance, Ivermectin (identified as curative in April 2020) works throughout all phases of illness because it both inhibits viral replication and modulates the immune response. Of note, chloroquine phosphate (Hydroxychloroquine, identified April 2020 as curative) is identified in the proposal as a SARS-CoV inhibitor, as is interferon (identified May 2020 as curative).

The gene-encoded, or "mRNA," vaccines work poorly because they are synthetic replications of the already-synthetic SARSr-CoV-WIV spike proteins and possess no other epitopes. The mRNA instructs the cells to produce synthetic copies of the SARSr-CoV-WIV synthetic spike protein directly into the bloodstream, wherein they spread and produce the same ACE2 immune storm that the recombinant vaccine does. Many doctors in the country have identified that the symptoms of vaccine reactions mirror the symptoms of the disease, which corroborates with the similar synthetic nature and function of the respective spike proteins. The vaccine recipient has no defense against the bloodstream entry, but their nose protects them from the recombinant spike protein quasispecies during "natural infection" (better termed as aerosolized inoculation).

UNCLASSIFIED

UNCLASSIFIED

Furthermore, the EcoHealth proposal states that a "vaccine approach lacks sufficient epitope coverage to protect against quasispecies coronavirus."<sup>10</sup> Consequently, they were trying to make vaccines work by "targeted immune boosting via vaccine inoculators using chimeric polyvalent recombinant spike proteins."<sup>11</sup> The nature of using a spike protein vaccine with one epitope against a spike protein vaccine with a quasispecies may explain the unusual (and potentially detrimental) antibody response amongst the vaccinated to the new COVID variants.<sup>12</sup> Fundamentally, the knowledge the proposal provides signals that the risk of Antibody Dependent Enhancement (ADE) from vaccination should be evaluated with high priority, on top of the reality that single-epitope vaccines will have little effect against SARS-CoV-WIV, as indicated in the proposal.

The potential for SARS-CoV-WIV to deattenuate requires immediate attention. Live vaccines have been found to deattenuate in the past. If this is the case with SARS-CoV-WIV, then the mass vaccination campaign actually performs an accelerated gain-of-function for it. Since it is designed for bats off of a human-susceptible SARS-CoV, vaccinating humans against it actually pins its mutation back towards a more deattenuated human-susceptible form. Improving the SARS-CoV-WIV spike protein to gain robustness against monoclonal vaccines is one of the steps of the DEFUSE program. The mechanism to improve the SARS-CoV-WIV spike protein (other than direct engineering) is to challenge it against animals that have spike protein-only antibodies. The attenuated virus will either die or adapt its form to neutralize the spike protein-only antibodies. The intent was to perform this task against humanized mice and then "batified" mice. Instead, it was done with the world's population.

SARS-CoV-WIV is not meant to kill the bats, but to immunize them. This nature may explain its general harmlessness to most people, and its harmfulness to the old and comorbid, who are in general more susceptible to vaccine reactions. The asymptomatic nature is also explained by the bat vaccine-intention of its creators (a good vaccine does not generate symptoms). Such effects would be expected of an immature vaccine, or a vaccine being reverse engineered from a more virulent form into an attenuated form. The spike protein effect on ACE2 receptors exacerbates the harmfulness in accordance with age and comorbidity. The nature of SARS-CoV-WIV's deattenuation will also indicate future virulence, though knowing its nature at last neutralizes the threat as effective treatments can be applied with confidence.

3. DRASTIC and other scientists will clean up my description of SARS-CoV-WIV's nature and progression within the DEFUSE program. This information is sufficient for an investigative report and more than enough to correct the existing pandemic strategy. Previously, the nation did not know itself, nor the adversary in the pandemic conflict. Now it knows both. The problem can be framed appropriately and specifically against a confirmed hypothesis. Limiting disease transmission can be dropped as the implied strategic end, as it is not the actual problem,

UNCLASSIFIED

UNCLASSIFIED

nor is it actually feasible. The strategy will then align early treatment protocols and prophylaxis with the known curatives as ways and means. This course of action will achieve the strategic end of clinical resolution for those that are susceptible to the adverse effects from SARS-CoV-WIV inoculation.

4. I will inevitably be asked how I figured this out and how I discovered the documents. The pandemic response became the predominant focus of my fellowship efforts. DARPA worked a number of pandemic innovations and much of its team was familiar with biodefense. I had the opportunity to "sit in the back row" per se and observe and listen-in on the government's efforts. My obligation-light fellowship also allowed me to observe and read the field. This observation grew in scope to the point that it became a series of reports, like a military scout would prepare when tasked to investigate a problem.

These reports served as iterative thinking against the problem over many months. Eventually, I arrived at a hypothesis that what leaked from the WIV could be a bat vaccine or its precursor. It was feasible that the US would try to avoid a SARS-CoV outbreak by stopping it at its source, not by halting its infection amongst people, but by halting the infections amongst the bats. Americans are creative, even if imprudent, and technologically confident enough to try it. This concept seemed to fit within the PREEMPT program construct as well, and DRASTIC had discovered that some earlier specimens within the USAID PREDICT program were obtained in Africa and sent to the WIV. Moreover, the unusual nature and pathology of the virus hinted that it could be a vaccine or be vaccine-like.

A technological challenge as difficult as inoculating bats in China would be tried at DARPA first. The massive, "Manhattan Project"-level of information suppression executed by the government and the Trusted News Initiative indicates that it would be covered-up if something bad happened. The lab-leak hypothesis and squabbling between Senator Paul and Dr. Fauci indicated that the cover up was more localized. Further, an actual cover-up would be more disciplined with its paperwork. So I presumed that unclassified files would be concealed on a higher network and found them where I expected them to be. I understood what they were and their content, flushed the files off-site, and compiled this report.

PM SUMMARY SHEET  
SOURCE SELECTION SENSITIVE

Solicitation Number: HR001118S0017

Solicitation Title: PREventing EMerging Pathogenic Threats (PREEMPT)

PM Name: James Gimlett

Proposer: EcoHealth Alliance

Proposal Title: Project DEFUSE: Defusing the Threat of Bat-borne Coronaviruses

Proposal Identifier: HR001118S0017-PREEMPT-PP-019

I have reviewed the attached proposal and Evaluation Reports and find that this proposal is selectable based on the evaluation criteria included in the BAA. However, I am not recommending funding at this time based on the rationale provided below.

Funding Requested (by proposer):

Phase I	Phase II	Total
\$8,411,546	\$5,797,699	\$14,209,245

This proposal aims to identify and model spillover risk of novel, pandemic-potential SARS-related coronaviruses (SARSr-CoVs) in Asia, focusing specifically on known hotspot bat caves in China. In prior work under USAID Predict, the team identified high risk of SARSr-CoVs in specific caves in Asia. The project has a good running start since the hotspot caves already test positive, with high prevalence, for several SARSr viruses so the team won't be looking for needles in haystacks. The team will build on past surveillance work as well as some impressive work in developing geo-based risk maps of zoonotic hotspots based on past spillovers and ecological data. Two approaches are proposed to preempt zoonotic spillover through reduction of viral shedding in the bat caves: 1) Innate immune boosting to downregulate viral regulation; 2) targeted immune boosting via vaccine inoculations using chimeric polyvalent recombinant spike protein to protect against specific high risk viruses.

Two of three reviewers marked this proposal as Selectable. Key strengths are the experienced team and the selected coronavirus hotspot caves that show high prevalence for novel bat coronaviruses. Experimental in vivo and in vitro work is logically thought out and will be used to validate molecular and evolutionary models. Proposed preemption approaches, while somewhat conventional, have the advantage of a fast timeline for validation on bat or "batenized" mouse models. Multiple vaccine delivery mechanisms are proposed, including aerosolized spray, transdermal nanoparticle application, and edible adhesive gels. However, several weaknesses to the proposal were also noted. These include a lack of detail regarding data, statistical analyses and model development and how prior work will be leveraged and extended. Proposal also lacks clear decision points to assess the deployment and validation of TA2 preemption methods in the

Dear Associate for DAU/PA Pathogenic Threats/202 Pathogenic Threats (PPT),  
Please accept the following proposal to the Pathogenic Threats (PPT) project (ID: 11156017) from the PI for  
Project DEFTUS: Defining the Threat of Bat-borne Coronaviruses

### Project DEFTUS: Defining the Threat of Bat-borne Coronaviruses

Dear Project DEFTUS: Defining the Threat of Bat-borne Coronaviruses  
Administrator (Request ID: 514-209-243)

Thank you for your time, and I look forward to hearing from you. If you have any questions, do not  
hesitate to contact me, or my office, at any time.

Yours sincerely,  
Peter Duszak  
Project DEFTUS: Defining the Threat of Bat-borne Coronaviruses  
Administrator

## Project DEFLU2

Our strategy begins by a complete inventory of bats and SARS-CoV at our intervention test site cave complex in Yunnan, China that harbors bats with high-risk SARS-CoV. We will collect data from three caves in the system to inform a pre-intervention test site and avoid collateral damage. Our bat abundance and diversity, site of emergence and diversity, individual bat viral load, and age class; bat saliva genomics characterization of low- and high-risk SARS-CoV strains among bat species, sex, and age class; bat saliva virometry and marker capture data on bat home range and interactive movement; and monitoring of bat density, weather and seasonal changes in bat populations. We will use these data, natural enemies to build joint specie distribution models (JSDM) to predict bat species' composition of caves, and predict SARS-CoV diversity across S. China, South and SE Asia. These will be parameterized with ERAS's database of bat-host-viral relationships and estimates of zoonotic viral 'infection risk' bat species' biology. Inventory data on all bat caves in Southern China, the first SARS-CoV inventory from our cave test sites in Yunnan, and species distribution data for all bats. We will test and validate viral diversity predictions using data from >20,000 previously collected bat samples from 6 Asian countries under our USAID-funded PATCCT project. We will produce a prototype app for the warning to identify the risk of bats harboring dangerous viruses at a site. This 'spillover risk app' will be a field-detectable and user-tunable prediction. We will use surveillance data to predict risk of SARS-CoV quasi species (QSS), the Wuhan Institute of Virology team (WIV) will test bat feces, oral and blood samples for SARS-CoV by PCR. We will collect viral load data from fresh fecal pellets. SARS-CoV spike proteins will be sequenced, then recombination events identified, and isolates used to identify strains that can replicate in human cells. The Univ. N. Car. China (UNC) team will reverse-engineer the spike proteins of a large sample of high- and low-risk viruses for further characterization. This will effectively freeze the QSS we analyze at t=0. These QSS strains via spike glycoproteins will be synthesized, and their binding to human cell receptor ACE2 will be inserted into SARS-CoV backbone (non-D616, non-G61), and inoculated into humanized mice to assess capacity to cause SARS-like disease, efficacy of monoclonal therapies, the inhibitor GS-5734, or vaccines against SARS-CoV<sup>+</sup>.

We will use these data to build machine-learning algorithms to predict the capacity of QSS strains to infect human cells based on kinetic trials and experimental assays above. Using data on diversity of spike proteins, recombinant CoV, and flow of CoV via bat movement and migration, we will estimate a) evolutionary rates, rates of recombination, and capacity to generate novel strains capable of human infection. Finally, virus-host relationship and test home range data will be used to estimate spillover potential - extending models well beyond our field sites. We will validate model predictions of next jump risk by 1) conducting further spillover

protein-based binding and cell culture experiments, and 2) identifying whether designated high-risk SARS-CoV strains have already spilled over into people near our bat cave sites. Our preliminary work shows ~3% seroprevalence to be SARS-CoV in people at this site. We will test these previously collected human sera ( $n > 2000$ ) for presence of antibodies to the high- and low-risk SARS-CoV identified by our modeling, using Luciferase immunoprecipitation system (LIPS) assays we design against the SARS-CoV identified in this project<sup>18</sup>.

**Technical Area 2 - Diagnostic** - Diagnostic will build upon the diagnostic building on its pioneering work on bat immunity<sup>19</sup>, including identifying weakened functionality of innate immunity factors like STING, a central DNA-interferon (IFI) sensing molecule, that may allow bats to survive on *Macaca*, but not *orangutans* to survive<sup>20</sup>, and RNA, which is constitutively increased without damage<sup>21</sup>. We will trial the following, concurrently and independently, for efficacy and stability: 1) Activating TLR/TLR pathways to induce IFN induction & production of type-I IFN. A similar strategy has been demonstrated in a mouse model for SARS-CoV<sup>22</sup>, 2) Universal bat interference. Interferon has been used clinically in people<sup>23, 24</sup>, against filovirus<sup>25</sup>, and replication of SARS-CoV is sensitive to Interferon<sup>26</sup>, but cannot be increased to a high enough level for combating negative regulators. Bat Interferon is constitutively expressed but cannot be increased to a high enough level for combating negative regulators<sup>27</sup>. We will use CRISPR to 'silence' potential negative regulators and screen for compounds to repress this gene. 3) Activating dipeptidyl peptidase 4 production in bat saliva via Dipeptidyl peptidase 4-dependent and STING-TLR7-dependent pathway. Mammal bat STING tolerance/antifragility, suggesting these pathways are important in bacterial resistance<sup>28</sup>. We will directly target the pathway downstream of STING/TLR7, to promote viral clearance via 'modulating' a key CoV fragments to upregulate innate immune responses to specific CoVs - a partial step towards the targeted immune boosting work. We will develop ProT. Sarc (LUC) will lead the targeted immune boosting work. We will develop recombinant chimeric spike-proteins from known SARS-CoV<sup>9</sup>, and those characterized by T-cell receptor binding<sup>29</sup>, and use them as vaccines for delivery to bats<sup>30</sup>. In combination with immune-booster small molecules, we will use them to boost immune memory. In adult bats, particularly exposed to SARS-CoV, along the bat can indicate forward and backward testing. Recombinant S glycoprotein-based constructs with immunogenic blocks from across 18 SARS-CoV<sup>18</sup> strains should induce a broad-spectrum adaptive immune responses that reduce cross-reactive T cell responses<sup>31</sup>, bats and transmission risk to people<sup>32</sup>. Innate immune damping is highly conserved in all bat species tested to far. We will use the unique Qute-HuS

## Project DEFUSE

Actions now for (pre)epidemic preparedness to combat potential SARS-CoV-2 outbreaks.

A novel delivery system for our immune boosters made of **bat ACE2** and **implanted by [Dr. Agot] into the SARS-CoV-2 infected **Lipofectin** (Invitrogen) who has previously developed a unique approach to delivery using a locally acquired **infectious bat SARS-CoV-2** (the **Wuhan** virus) as a vector to deliver the **ACE2** gene to the apical nanoparticle [1]. A fully addable gene that does not mutually compete with endogenous ACE2. This will be used to treat patients for caravans and 4) automated spray triggered by sensor and movement detectors at critical cave entry points. We have extensive preliminary data on these techniques for wildlife, including vouchering bats against their bat, successful delivery, colonization and spread in wild vampire bats. We will use the **Wuhan** bat gene for caravans and will use the same to treat the **caravans** using the biomarker **rhodamine B** (which fluoresces red in the hair on contaminated) to assess uptake. The most optimal deployment of protection will be tested on **local bats** at our test cave sites in **Tunisia**, using the most effective (immuno modulation) preparations. Any optimizations from experimental and control areas will be surveyed (longitudinal) for overall load factors and after deployment trials. **EDU** has had urgent access to bats from our **partner** at the **Yunnan Forestry Department** and **Central for Disease Control**, following our proven track record of highly obfuscating **EDU** and **DoD** **ACDC** **sep** for animal research. We will model optimal strategies to maximize treatment efficacy for **TZ2**, using stochastic simulation modeling of viral circulation dynamics at our sites, informed by field and experimental data. We will estimate frequency and population coverage required for our intervention, and model the time period of viral suppression, until re-colonization or a violation leads to return of a high-risk SARS-CoV-2.**

### Deliverables

- Open source models and App **Yunnan** **geographical** and **host-specific** for SARS-CoV-2 for novel SARS-CoV-2s
- Experimentally validated genotypic-phenotypic models of spillover for viral transmission
- Proven technology to modulate bat innate immunity to reduce viral shedding
- Tested and validated delivery mechanism for bat cave usage including vouchering in **quarantine** bat host-pathogen systems (e.g. **rabies**, **WNV**)
- Proof-of-concept approach to transiently reducing viral shedding in wild bats that can be adapted for other systems including a **bat virus**.

### Section 3.1.1.3. D. TECHNICAL PLAN

#### Technical Area 1

**Character of site and model host-virus dynamics.** For the past 14 years, our team has conducted CoV surveillance in bat populations across S. China, resulting in 1,510 unique SARS-CoV-2s. In ~10,000 samples (25% prevalence, including multiple individuals in the same viral strain), **17** bats and a **17**-bacter species prevalence up to 10.5% bat SARS-CoV-2s are genetically diverse, especially in the **S** gene, and most are highly divergent from SARS-CoV. However, our test cave site in Yunnan Province, harbors a **quasibreeding** (Qb) population **represented** that contains all the genetic components of epidemic SARS-CoV<sup>1</sup>. We have isolated three strains there. [WV1],

## Project DEFUSE

### PROBLEMS

**WV1b** and **WV1c**) that utilize other SARS-CoV, do not contain two deletions in the receptor-binding domain (RBD) of the spike, have (or higher sequence identity to SARS-CoV [Fig. 1], use Human ACE2 receptor for cell entry, as SARS-CoV does [Fig. 2], and replicate efficiently in various bat and human cells. Including primary human lung alveolar cells, similar to epithelial SARS-CoV<sup>2</sup>. Chimera (recombinant) with then SARS-CoV-2 genes inserted into a SARS-CoV backbone, and synthetically reconstructed full length SARS-CoV and WV1 cause SARS-like illness in hampered mice (not expressing human ACE2), with clinical signs that are not associated with SARS-CoV infection antibody response [1]. People living up to 8 kilometers from our test cave have SARS-CoV antibody (>26% seroprevalence) [2]. **Appendix 1A** lists data, phylogeny of SARS-CoV, and evolutionary analysis of bats and their CoV (input), **Figure 1** is the bar chart, and **Rhinolophus** spp. bats in the likely origin of this SARS-CoV clade, and are a clean-and-pleasant disease for the emergence of a SARS-CoV from the current CoV. The **Administration** esp. **but** their human disease victim occur across Asia, Europe, and Africa. Thus, while **EDU** **bioethical** will focus on **in vitro** in **Yunnan** China, our **bioethical** to evidence the hit of these virus will focus on **in vivo** **infectious** **bioethical** **bioethical**.

Project ID: 00015

ПОДАЧА ВОДЫ

insignificant (<5% prevalence) role in viral dynamics. We will use *Microelephant* spp. here using harp traps and mist nets during evening hours, collect rectal swabs and whole blood samples 1-2 per day using a sample technique to avoid cross-contamination, and do a 2 mm wing punch biopsy for host DNA sequencing. The adeno receptor gene sequence, interface genes - 3 individuals for 50 species, and phylogenetic analyses. This will be substantiated by reproductive status (pre-ovulatory, pregnant and post-parturient) and physiological status (e.g. lactating, non-lactating, non-reproductive).

secondary leaves will be surveyed using permanent plots (estimated to give 10% error). At least 100 data on species composition for targeting of internal modulation treatments in T42 (Fig. 3). Sampling quota will be adjusted based on lab and model results to optimise use of resources.

ପାତ୍ରିକା

To estimate phylogenetic scales of biodiversity in India, we will include data from 2 000 viral metagenomes (1000 Indian and 1000 from >10 000 individuals in samples in G. Asian countries (INA, and 500 PLoS CT funded). For detailed construction of viral metagenomic predictions, we will validate models against a 20% validation subset of data and field data. Prioritize a app for the user interface, drawing on experience from the field and available mobile platforms (Android, iOS).

5

## HR00211850017 EcoHealth Alliance (part 2)

### Project DEFUSE

warfighter that identifies probability of dangerous viral spill-over, including over from bats as a site. We will use outputs from our spatial risk modeling, observational and predicted host-viral associations, open-source species and pathogen ontologies, and app-directed crowd-sources to calculate data to ground-truth and refine our predictive capacity. This app will be updated in Y2 and Y3 to incorporate additional risk data from bat-virus bleeding assays and SARS-CoV surveys. We will use EHA's risk-ranking algorithm to display critical areas of high risk based on localization features, such as human population, host and pathogen characteristics. The app will collect user GPS location data and predict bat species distribution and community transmission estimated from our ISPR. These will be refined with real-time surveillance data collection, and without the need to enter cave sites using mobile phones enabled high-frequency microphones for 'real-time detection'. Validated and trained with reference calls using convolutional neural networks, unidentified bat species will be automatically linked with viral diversity data from EHA's host-pathogen database and SARS-CoV data from DEFUSE to deliver high-risk pathogen risks, displayed as pathogen-centric, bat-centric or map-centric views, with proactive alerts when critical information is updated and be available and documented on GitHub<sup>1</sup>.

Methodology will monitor spatial and biological areas in case of active and novel infections, areas found in bats allowing DoD personnel to quickly identify areas high spill-over risk sites and facilitate delivery of resources to respond to and mitigate when necessary.

SARS-CoV-2 detection, sequencing and recovery. We will screen samples for SARS-CoV nucleic acid using four Pan-CoV consensus one-step semi-nested RT-PCR assay targeting a 440 nt fragment in the RNA-dependent RNA polymerase gene (poly) of all known α and β-CoVs<sup>2</sup>, and specific assays for known SARS-CoV-2<sup>3,4,5</sup>. PCR products will be gel purified, sequenced and qPCR performed on SARS-CoV-positive samples to determine viral load. Full-length genomes of 5 genes of all 5 SARS-CoVs will be high-throughput sequenced followed by genome walking<sup>6,7,8</sup>. We will analyze this 5 genes to identify 5 bind to bind human ACE2 by BioSieve or via embryogenic. Synthetic of Coeviric Novel SARS-CoV-2<sup>9</sup>. We will commercially synthesize SARS-CoV 5 glycoprotein genes designed for insertion into 3'-C14 or 5'-V15 molecular clamp baculovirus (98% and 97% S-protein identity to epidemic SARS-Urbani). These are 853-9, and the select genes of subclone to F2GQ (they use bat SARS-CoV backbone which are exempt) and the pathogenic to hACE2 transgenic mice. Different baculovirus strains increase recovery of viable virus identification of barriers for RNA recombination-mediated gene transfer between strains<sup>10</sup>. Recombinant viruses will be recovered in vero cells, or in mouse cells over-expressing human, bat or chimp ACE2 receptors to support cultivation of viruses with a weaker ABO-human ACE2 interface. Discovery of Anti-biotin SARS-CoV<sup>12</sup>. We will compile sequencing/HiSeq data from a panel of closely related strains ( $\sim$ 5% nucleotide variation) and compare full length genomes, scanning for unique SNP representing sequencing errors<sup>11</sup>. Consensus candidates will be synthesized commercially (e.g. BioBasic), using established techniques and Sanger-length RNA and electroporation to recover recombinant viruses<sup>12</sup>.

## HR00211850017 EcoHealth Alliance (part 1)

### Project DEFUSE

Predicting strain-specific SARS-CoV spill-over risk. We will combine detailed environmental characterization of Q5 or our test case sites with state-of-the-art metahypochthonious Bayesian approach models that enables us to predict the long-term probability of future SARS-CoV with human infection potential.

Model will be parameterized with experimental data from a series of assays on the 5 genes of bat SARS-CoV<sup>13</sup>. Together in iterative steps, our prior data will act as baseline to parameterize a spill-over risk modeling<sup>14,15,16</sup>. This will be supplemented by characterization of isolated viruses under DEFUSE (as Wily), approximately 15-20 bat SARS-CoV spike protein/year (at UMC, WIV, and  $\sim$ 10 bat SARS-CoV strains available). In our prior work and not yet examined for spill-over potential. All experiments will be performed in replicate and data fed to models in real time:

Experimental assay on SARS-CoV Q5 jump potential<sup>17</sup>: B, night, day, stratification, and stratification<sup>18</sup>. Viral entry inhibition, spike protein, and spike protein<sup>19</sup>. Virus entry inhibition, spike protein, and spike protein<sup>20</sup>. To select Q5 for further characterization of SARS-CoV<sup>21</sup>. We will use structural modeling of SARS-CoV protein binding to ACE2 receptor<sup>22</sup>. Mutations in the RBD<sup>23</sup>, and receptor SARS-CoV cell entry and cross-species infectivity. Mutation in the S-RBD-ACE2 molecules or spike protein processing will prevent entry of SARS-CoV protein into cells for spike protein binding<sup>24</sup>.

Strain will be characterized. Single amino acid variations could dramatically alter these phenotypes and we will evaluate the impact of low abundant, high consequence micro-variation in the RBD using bioassays to identify low abundant Q5 variants encoding micro-variants relevant to ACE2 binding. We will conduct *in vitro* pseudovirus blocking assays, using established techniques<sup>25</sup>, and live virus binding assays (at WIV to prevent disease and unnecessary dissemination of viral culture) for isolated strains. Initial model predictions based on these data inputs will be used to guide strain selection for further characterization. In vitro testing of strains<sup>26</sup>. All chimp-like viruses will be sequenced, verified and evaluated for: i) ACE2 receptor usage (host species) in vitro; ii) Reprof in primary HAE, iii) Sensitivity to broadly cross-reacting human monoclonal antibodies (mAb) and unique epitopes in the RBD<sup>27</sup>.

Antibodies<sup>28</sup> human immunoprotein in hamsters should receive unique epitopes in the RBD<sup>29</sup>. Should some isolates prove highly resistant to all mAb panel, we will evaluate cross-neutralization against a limited number of human SARS-CoV serum samples from the Toronto outbreak. Chimp-like viruses that encode novel 5 genes with spill-over potential will be used to identify SARS-CoV strains for recovery in full genome (search within viruses). In vivo, SARS-CoV strains in animals will be infected intranasally with  $1.0 \times 10^6$  PFU each SARS-CoV, clinical signs (weight loss, respiratory function, mortality, etc.) followed for 8 days

p.i., and sacrificed at day 2 or 6 p.i. for viroscopic, immunohistochemistry of the lung and for 22-parameter complete blood count (CBC) and immunohistochemistry of the lung and for 22-parameter complete blood count (CBC) and bronchial alveolar lavage (BAL). Yolkization with full-length SARS-CoV genome. We will generate results from chimeric viruses, by re-combining full-length genome versions, testing whether infection & genome sequence alterations in full-length SARS-CoV spike protein, OR for full-genome characterization will be sufficient to reflect strain differences in antigenicity/acceptor usage, growth in human cells and on the genome. We will test growth in primary cell cultures and in Huh7 cells in ACE2 transgenic mice. We anticipate recovering ~2-5 full-length SARS-CoV genome with more combinations of mutations. **2.2.1.2. Synthetic Modification** We will synthesize SARS-CoV with novel combinations of mutations to determine the effects of specific amino acid changes, and the jump potential of future and unknown recombinants. **RBD deletion: 5' small deletion.** We will do the same in the SARS-CoV RBD after risk of human infection. We will analyze the functional consequences of these RBD differences on SARS-CoV ACE2 receptor usage, growth in HAE cultures and *in vivo* pathogenesis. First, we will delete these 5' ends, sequentially and in combination. In SHCoV and SARS-CoV-Urban, we will anticipate that the introduction of deletions will prevent virus to attach to human ACE2 and in parallel, we will evaluate whether RBD deletion impair restore the ability of low risk strains to use human ACE2 and grow in human cells. **2.2.2. Glycogen and Glycosylation Sites:** After receptor binding, a variety of cell surface or endosomal proteases<sup>37</sup> cleave the SARS-CoV S glycoprotein causing massive changes in structure<sup>38</sup> and activating fusion-mediated entry<sup>39</sup>. We will analyze all SARS-CoV S gene sequences for appropriately conserved proteolytic cleavage sites in S2 and for the presence of potential furin cleavage sites<sup>24,25</sup>. SARS-CoV with mismatches in proteolytic cleavage sites can be activated by exogenous trypsin or cathepsin L. Where cleavage mismatches occur, we will introduce appropriate human-specific cleavage sites and evaluate growth potential in Vero cells and HAE cultures. In SARS-CoV, we will obtain several of these sites based on pseudovirus particle studies and evaluate the impacts of select SARS-CoV S changes on virus replication and pathogenesis. We will also review disease sequence data for low abundant high risk SARS-CoV that encode functional proteolytic cleavage sites, and if so, introduce these changes into the appropriate high abundant low risk parental strain. **2.2.3. Glycosylation:** Some glycosylation events regulate SARS-CoV particle binding OC-SD1/OC-SD1, alternative receptors for SARS-CoV entry into macrophages or monocytes<sup>40</sup>. Mutations that introduced two new N-linked glycosylation sites may have been involved in the emergence of human SARS-CoV from civet and raccoon dogs<sup>37</sup>. While the sites are absent from civet and raccoon dog strains and clade 2 SARS-CoV, they are present in WHV1, WHV6 and SHCoV, supporting a potential role for these sites in host jumping. To evaluate this, we will sequentially introduce clade 2 disrupting residues of SARS-CoV and SHCoV and evaluate virus growth in Vero cells, nonpermissive cells ectopically expressing DC-SIGN, and in human monocytes and macrophages anticipated reduced virus growth efficiency. We will introduce the clade 1 mutations that result in N-linked glycosylation in f5c237 RBD deletion

modified strains, evaluating virus growth efficiency in HAE, Vero cells, or nonpermissive cells + ectopic DC-SIGN expression<sup>37</sup>. *In vitro*, we will evaluate pathogenesis in transgenic ACE2 mice. **2.2.4. Abundant Glyco-acceptor-sites:** We will structurally model and identify highly variable regions in the SARS-CoV S RBD, use commercial gene blocks to introduce these changes singly and in combination into the S glycoprotein gene of the low risk, parental strain and test ACE2 receptor usage, growth in HAE and *in vivo* pathogenesis.

Fig. 7. A simplified directed graph of a Bayesian network model representing the causal relationships between host data, model predictions, and results.

Network machine-learning to predict spillover potential of high-risk SARS-CoV strains. We will use experimental data from above to build genotype phenotype models of bat SARS-CoV spillover potential. We will use Bayesian Network Models (BNM), fit via MCMC methods<sup>40</sup>, to predict spillover risk based on bat SARS-CoV genotype data (presence of deletions in RBD, antigenic binding and glycosylation sites etc.) and the ecological traits of hosts - integrating data on multiple interacting processes and SARS spillover potential to generate overall spillover probabilities. The Bayesian approach will allow us to update our models iteratively as new data is acquired, and use interim model predictions to refine which experiments to prioritize to maximize predictive ability<sup>41</sup>. We will control for experimental conditions (assays on live viral isolates, full-genome or synthetic SARS-CoV variants, and the molecular backbone of the latter). Trials will be used as inputs to SARS's causal graph, to predict latent variables representing independent predictors that contribute to SARS-CoV infection in new hosts. A spillover model will be built to predict human infection, and infection rates, all measured by our lab assays<sup>42</sup>. There, in turn will be as predictors for the ultimate patterns of host pathogenesis and host jumping potential<sup>43</sup>. We will publish a work on these genetic traits to put informative priors on strength and direction of interactions in the causal graph. We will use prior-knowledge model simulations to select target sequences from our samples<sup>44</sup> for sequencing and select the most promising variants in the final model.

Model validation using SARS-CoV serology from human auto-collected human samples and surveillance data. Active spillover of SARS-CoV in our study region enables us to measure active spillover risk to validate our model of SARS jump potential. We will gather data on viral SARS antibodies found in the ~1 billion population using LUMI assays on ~2,000 previously-collected human sera (prior). Data will be from people living close to our test cave sites in Yunnan Province, a sub-sample of which have a 4.27% seropositivity to bat SARS-CoV<sup>45</sup>. The BBS for

This work is current and covers proposed Direct testing. We will use LIPS assays targeting Neth- and low-pathogenic avian influenza virus (St. Louis/9/CS), as well as previously known SARS-CoV-1. We will also test for different high- and low-path SARS-CoV-1 N, into pICH4-1 vector (LIPS vector), first assessing N-specific antibodies to determine their potential cross-reactivity in a LIPS assay.2) determine LIPS assay specificity by producing polyclonal sera via injection of recombinant protein or attenuated virus into chicken.3) Simultaneously, we assay by incubating antisera with either reactive positive serum samples and the antigen antibody complex eluted using protein A/G beads.4) Positive LIPS positive sera reacted by spike protein based LIPS and viral neutralization assay. As a confirmatory test, the positive samples from LIPS will be validated by virus neutralization assay. We will use these LIPS assays to test animal samples for presence of antibodies to H1N1, H3N2, and avian influenza virus (St. Louis/9/CS). We will validate presence of IgM potential and extend the ability to predict actual infection probabilities by modeling human contact rates with Luts. We will use ecological data on humans and human behavior and survey data collected previously on this individuals to estimate vehicle contact in predicting exposure measured by our LIPS assays.

Even better, by modelling and simulation to predict potential targets. Our Bayesian network modelling will generate data for the epistemic risk of Q3 sequences we identify. To examine this associated with the total UK population, we will model and simulate evolutionary processes to identify likely viral Q3 that our sampling has not captured, and viral Q3 likely to arise in the future [105]. We will use a large dataset of SARS-CoV-2 substitutions in recent and to genome-wide variants, using coalescent and molecular clock models with a Bayesian hierarchical framework [106]. We will estimate SARS-CoV-2 recombination rates at the case population level using these data and Bayesian inference [107]. We will apply BDP<sub>1</sub> similarly, and bootstrap to identify recombination hotspots within the SARS-CoV-2 genome as done previously [108], now extended to the full genome. Using these estimates we will simulate the evolution of the SARS-CoV-2 genome using a forward-on-a-sprach implemented in a simulator that model specific Q3 virus mutations [e.g. ViraMoPS<sup>14</sup>], then will project the rate at which new combinations of genetic traits can spread in viral populations [109].

Complex recombination rates among cases and bar communality rates. Our forward-inferenced results will provide a pool of likely unknown and future Q3 sequences. Using these and our SIR model for spillover risk, we will predict the Q3 most likely to arise and have a spillover and pathogenetic potential. We will use evolution by simulation results to iteratively improve our Bayesian network model. The number of genetic traits with pathogenetic risk for prediction of pathogenicity is large, so we will perform variable reduction using tree-based classifiers, training highly co-occurring traits as joint clients for prediction. We will separate these clusters from all SARS-CoV-2 individuals and prior work. As trait clusters may be modified through recombination, we will use our forward-evolutionary modelling to predict how trait clusters will change, retaining only those with increased predictive power unknown or Q3, genetics. This will enable a track-off between increased predictive power based on current samples and generalisability to future strains that have not yet arrived.

100

**Intrinsic modulation approach to reducing bat SARS-CoV spillover risk.** Our work shows that the following unique immunological features of bats may explain their capacity to harbor high viral loads with minimal clinical signs: (a) bats maintain constitutive high expression of tRNA, that may respond to and restrict viral infection; (b) several interferon pathway genes are dampened (e.g. STING (a central cGAMP-DNA-sensor molecule to induce interferon)) (c) independent and TLR7 dependent pathways; (d) the tRNA dependent inflammatory pathway is compromised, and key inflammatory response genes like MDA5 are not present in bats<sup>12</sup>. These characteristics may be due to bat immune-sensing pathway adaptation by constitutively suppressed TLR7 in bats, resulting in low T cell activation due to lower viral tRNA. Second, damage and interference and inflammasome responses will result in lower cytokine responses that are required to trigger TLR7 cell dependent negative immunity (i.e., anti-viral responses), ultimately resulting in suppression of viral replication and shedding. We and others have demonstrated a *proof-of-concept* of this phenomenon: Experimental Marburg virus infection of Egyptian fruit bats (a natural reservoir host), resulted in widespread tissue distribution with low viral load, brief viraemia, low seroconversion and a slow and body sites that waned quickly, suggesting that long-term destruction is not fatal here<sup>13</sup>. Poorly regulating an antibody response occurs after experimental infection of bats with Tzecmilia virus<sup>14</sup>, and in our studies of experimental infection of bats with SARS-CoV (Vero, unpubl.). We also successfully showed that bat IgA antibodies can neutralize bat SARS-CoV<sup>15</sup>. We hypothesize that use of immune modulators that upregulate the naturally low inflammasome output of bats to their Lumen will transiently upregulate viral replication and, hopefully, reduce the bat Lumen risk. We further hypothesize that because *Alpha* bat SARS-CoV does not form clathrin-coated vesicles in a population will have been exposed to a range of SARS-CoV in our sites. Specifically, target site selection based on their relative immunogenicity (immuno-strength) to high-risk viral strains may lead to the development of high-risk strains. We will evaluate two immune modulation approaches to reduce spillover of SARS-CoV in bats: 1) Broad-spectrum Janssen Scirocco anti-angiotensin II receptor (AT1) agonists or antagonist in bats, is up-regulating tRNA molecules for SARS-CoV (we will a poly-tRNA molecule like the TLR7-agonist) and 2) Immune Boosting (Barts, UK). In the broad-spectrum anti-viral approach, the peptide will be applied in the presence of chimeric immunogens to activate immune memory in adult bats and boost clearance of high-risk SARS-CoV. We will use novel chimeric polyvalent recombinants and preclinical in microprimate animal studies for oral delivery and/or virus subunit and immune bonding strategies where chimeric recombinant SARS-CoV 5.8 kDa expressed by recombinant poxvirus. Both forms of work will begin in year 2, and run parallel, to be assessed competitively for efficiency, cost, and feasibility, and success. Data from captive animal trials will be used in the bat cage in our test cage in Yunnan. The finding of low tRNA immunity across bats suggests that immune bearing could be broadly applied to bat genera and viral families.

**Microscale's immune boasting (Duke-HHS).** We will work on the following key leads to identify the most effective approach to up-regulate innate immunity and reduce viral loads. Top-line **Category 1: Early-life factors (HLA) effects.** Our work indicates a robust response in live bats to 7/10-HMfR-Ba plp1C as measured by transchelomites on spleen tissue [Fig. 3], liver, lung and lymph nodes, with matched plasmatics to characterize immune activation in vivo. These activation profiles will be used to assess bat immune response to different stimuli and identify those which lower viral load in our experimental system at Duke-HHS (DeJong).

**Category 2: Factors from Andigen Pathway.** Analysis of more than 1000 samples from Duke-HHS with either LPS or synthetic 2-Deoxy-N-acetyl-beta-D-glucosamine (2DG) over several beta 1-hydroxylases are present and synthesize unique modifications of many pathways.

We will also stimulate the RIG-I pathway, a mimic of the natural RIG-I signalant that will activate functional type I IFN production pathways, as shown in a mouse model that cleared SARS-CoV, IAV and H1N1<sup>13</sup>. We will design a conserved universal bat interferon protein sequence with artificial gene synthesis and produce recombinant proteins by cleavable-affinity-tagged expression of supernatant from our expression bat cells, as used previously for recombinant Marburg virus peptide-dependent response to the ligand, allowing the use of IFN throughout broad geographical and ecological environments and across many bat species. We have already produced recombinant non-universal, trigenic, bat IFN that induce appropriate immune activation [Fig. 9]. This ligand has been shown to reduce viral titres in humans, ferrets and mouse models intranasally and orally<sup>14,15</sup>. Interferon has been used clinically in humans as an adjuvant to other drugs or as an antiviral, & against fibrosis<sup>16</sup>. Interferon is known to be toxic, therefore we will carefully examine dose tolerance in bats and assesses clinical effects of the treatment. We have shown that replication of SARS-CoV is sensitive to IFN treatments<sup>17</sup>. The successful delivery, intrinsic activation and outcome on the

**Antibodies/peptides/peptides/peptides:** We will design a conserved universal bat interferon protein sequence with artificial gene synthesis and produce recombinant by cleavable/affinity-tagged or purification of supernatant from over-expressing bat cells, as used previously for recombinant *Papaya* effects pIFN- $\alpha$  33A and pIFN- $\beta$  3/4. Utilization of a universal pIFN for bats will overcome species-dependent response to the ligand, allowing the use of IFN throughout broad geographical and ecological environments and across many bat species. We have already produced recombinant non-natural, tagged, bat IFN that induce appropriate immune activation [Fig. 9]. This ligand has been shown to reduce viral titers in humans, ferrets and mouse models intensitely and rapidly. <sup>10</sup> Interferon has been used clinically in humans as an antiviral drug <sup>11</sup> and as an antitumor drug <sup>12</sup> as well as an anti-viral agent. <sup>13</sup> Interferon is a safe and effective curative measure when universal drugs are unavailable, e.g. against filovirus. <sup>14</sup> Interferon is known to be toxic, therefore we will carefully examine dose tolerance in bats and assess clinical effects of the treatment. We have shown that replication of SARS-CoV is sensitive to IFN treatments. <sup>11</sup> The successful delivery, intrinsic activation and outcome on the

Antibody Treatment	IgM Synthesis Rate (cpm/10 <sup>6</sup> cells/min)	IgG Synthesis Rate (cpm/10 <sup>6</sup> cells/min)
IgM alone	100	100
IgM + IgG	~60	~60
IgM + IgM	~40	~40
IgM + IgM + IgG	~20	~20

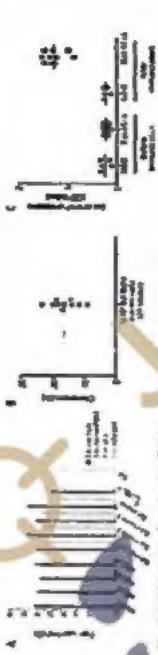

**Boosting bat *beta*-*defensin* but not *cathepsin G* in *in vitro* coculture. Uniquely, bat *beta*-*defensin* is naturally constitutively expressed but cannot be induced to a high level, indicating a negative regulatory factor in the bat interferon production pathway.<sup>254</sup> We will use *Primates* (clade CII) as a literary pool that we have generated consisting of multiple RNA elements in every one of the *P. aethiops* genome (Wang, unpubl.).**

[Page 111] **Людмила Альбина (Деца)**

प्राचीन देवता

data). Genes affecting influenza replication in *bt* cells have already been identified using this library. Using ChIP-seq we will identify negative regulator genes and screen for compounds targeting them to boost the infectivity of the  $\beta$ 1H protein in a shorter time-frame. Based on previous work<sup>10,11</sup>, it is highly likely this will be a conserved pathway across all bats. Activating conserved *bt*-specific immune pathways which include DVA-57KDa-dependent and *bt*-dependent pathways. We have shown that *bt* cells have STING on recombinant of Alm1A and functional NLRP3 homologs (not found in humans) functioning, suggesting these pathways are important in bat viral clearance. By identifying small molecules to directly activate pathway components of STING or TLR3/7/8, such as TLR3 activation, we will activate this defense by interferons, promote viral clearance and, we hypothesise, significantly reduce viral load in *bt* cells. Validation in a *bt*-negative model, *Virusus* CoV, shows efficient infection and replication based on the number of *bt* cells infected, defective entry and replication using mouse or *bt* cells in part to entries in DPP4 and ACE2 receptors.

**Reciprocal validation of the best protein/propeptide to elicit an effective immune response.**

target immune system (lung) to deposit targets against SARS-CoV-2. We will incubate with chimeric 3D hypoprotein in the presence of the breastmilk Ig immune boosting agonists above. We will develop a tool (Group 2b SARS-CoV chimeric 3D glycoprotein that encodes neoplasia) donation from phylogenetically distant strains (e.g., Urbani, H91, BCoV79, ~25% diversity). The chimeric 3D protein efficient aspiration will be introduced in the HKU13 backbone full length protein, and it will provide immunity against infection Group 2b strains. We will develop robust aspiration systems for SARS-CoV chimeric 3D using biologic expression in vitro. We will work with Dr. Abhilek (UNIC-PHARMACEUTICALS) who has developed novel microorganism delivery systems (mucosal immune agonists) that can be applied to breastmilk immune boosting strategies.
